Background: The characterization of progenitor/keratinocyte stem cells (KSC) remains an unachieved goal. A previous study showed that rapid adhering cells to collagen IV had the characteristics of putative progenitor/KSCs. Objective: The purpose of this study was to investigate the genetic expression of rapid adhering cells compared to non adhering cells to determine the characteristic of KSCs. Methods: We isolated rapid adhering cells representative of KSCs from non adhering cells representative of transient amplifying cells. In addition, we differentiated cells from human tonsilar keratinocytes utilizing the adhering capability of the KSCs to collagen IV. Annealing control primer based differentially displayed polymerase chain reaction (PCR) was performed as well as Western blot analysis. Results: The levels of mitochondria-related gene expression were low in the rapid adhering cells compared to the non adhering cells. Mitochondrial complex I, COX IV, peroxiredoxins (I, II and IV) and mitochondrial membrane potential were all low in the rapid adhering cells compared to the non adhering cells. Conclusion: Using an adhesion method on human collagen IV-coated plates, our results suggest that reduced mitochondrial function may be an important characteristic of KSCs. INTRODUCTION

Human keratinocytes are constantly renewed and replaced by a population of keratinocyte stem cells (KSC) located in the basal layer of the epidermis. KSCs are responsible for the maintenance of skin cell homeostasis, and are believed to be resistant to noxious environmental stimuli; they give rise to fast-dividing transient amplifying cells (TAC) committed to terminal differentiation, while retaining their self-renewal capacity. Although α 6 integrin, β 1 integrin, and p63 have been reported as markers for KSCs, FACS using these markers has not provided practical yields of viable KSCs. An adhesion method has been developed using the rapid adhesiveness of KSCs to collagen type IV, fibronectin and extracellular matrix, and has been assessed using many different methods of varying sensitivity, complexity and time. Kim et al. in 2004, suggested that rapid adhering (R.A.) cells in the adhesion assay represented KSCs and therefore, this assay could be used to isolate KSCs. Our previous work using this adhesion assay showed that R.A. cells had the characteristics of KSCs including a small number of cells with undifferentiated morphology, and a stronger expression of α 6 integrin, β 1 integrin, β catenin and p63. The goal of this study was to use the adhesion assay and annealing control primer based differentially displayed polymerase chain reaction (PCR) to further characterize the KSCs. We evaluated whether the ad-
Reduced Mitochondrial Properties in Putative Progenitor/Stem Cells of Human Keratinocytes

MATERIALS AND METHODS

Culture of normal human keratinocytes and adhesion assay

Primary cultures with keratinocytes from three different tonsillar tissues were established. The keratinocytes were cultured in keratinocyte growth medium (Cambrex, Walkersville, MD, USA) as previously described. The third passaged cells were placed in human collagen type IV (Sigma-Aldrich, St. Louis, MO, USA) coated dishes and incubated for 10 min as previously described. Rapidly adhering (R.A.) cells were collected after vigorous washing and considered to be KSC fractions. After 90 min, suspended (non adhering, N.A.) cells were collected and considered to be TAC fractions that were post-mitotic differentiated cells.

Annealing control primer (ACP)-based polymerase chain reaction (PCR)

Total RNAs extracted from the R.A. and N.A. samples were reverse transcribed for 1.5 h at 42°C in a final reaction volume of 20 μl containing 3 μg of the purified total RNA, 4 μl of reaction buffer (Promega, Madison, WI, USA), 5 μl of dNTPs (each 2 mM), 2 μl of 10 μM dT-ACP1 primer (5'-CTGTGAATGCTGCGACTACGATTIIIIIIIT(18)-3'), 0.5 μl of RNasin (RNase Inhibitor (40 U/μl); Promega), and 1 μl of murine leukemia virus reverse transcriptase (200 U/μl; Promega). The DEGs were screened by the ACP-based PCR method using GeneFishing™ DEG kits (Seegene, Seoul, Korea). The PCR protocol for second-strand synthesis was one cycle at 94°C for 1 min, followed by 50°C for 3 min, and 72°C for 1 min. The second-stage PCR amplification protocol was 40 cycles of 94°C for 40 s, followed by 65°C for 40 s, 72°C for 40 s, followed by a 5 min final extension at 72°C. The amplified PCR products were separated on a 2% agarose gel stained with ethidium bromide. The differently expressed bands were extracted and cloned into a TOPO TA cloning vector (Invitrogen, Carlsbad, CA, USA) and complete sequences were extracted and cloned into a TOPO TA cloning vector.

RESULTS

ACP-based PCR for rapid adhering (R.A.) and non adhering (N.A.) cells

The products separated for the DEGs on agarose gels showed 10 different cDNA bands (C1-C10) by hatched blastocyst-specific expression (Table 1). The 10 different DEG clone found by comparing the bands of the R.A. and N.A. cells included four mitochondrion-related genes: C1

Western blotting

Total cell lysates (20 μg protein) form R.A. and N.A. cells underwent 8~16% SDS-PAGE and were transferred onto a PVDF membrane. To compare the differences in the expression of R.A and N.A. cells, other cells that had intermediate adherence ability were removed. The DEGs, by ACP-based PCR, showed primarily mitochondrial-related genes. Therefore, we investigated representative proteins related to mitochondrial biogenesis and to the respiratory chain including: mitochondrial complexes I to V, and peroxiredoxins 1 to 6. The primary antibodies included antibodies against mitochondrial complex I (NADH ubiquinone oxireductase 39 kDa a subcomplex 9, NDUF9), complex II (Succinate-ubiquinone oxireductase 70 kDa flavoprotein, SDHA), complex III (Ubiquinone-cytochrome c, core II, UQCR2), complex IV (cytochrome C oxidase subunit I, COXI and, subunit IV, COXIV) and complex V (ATP synthase, F1 complex a, ATP5A1) (all Invitrogen). In addition, antibodies against peroxiredoxins 1~6 (Ptx 1~6) (Lab Frontier, Seoul, Korea), S-100 calcium binding protein A8 (Santa Cruz Bio, Santa Cruz, CA, USA) and β-actin (Sigma-Aldrich) were evaluated against the loading of proteins. The membrane was incubated with goat anti-mouse IgG or goat anti-rabbit IgG conjugated with horseradish peroxidase (Santa Cruz Bio). The immunoblots were developed by the ECL reaction (Amersham, Piscataway, NJ, USA).

Tetramethyl-rhodamine ethyl ester (TMRE) and mito-tracker staining

R.A. and N.A. cells were stained with 150 nM TMRE (Invitrogen) in the dark at 37°C for 30 min. The cells were then washed, resuspended in phosphate-buffered saline containing 15 nM TMRE, and analyzed by flow cytometry (FACS Calibur, BD Biosciences, Franklin lakes, NJ, USA). For the mitotracker staining, the cells were cultured in chamber slides overnight, then washed and fixed with 3.7% paraformaldehyde (Sigma-Aldrich). The cells were stained with 500 nM of MitoTracker Orange CMTracker Ros (Invitrogen) in the dark at room temperature for 20 min after permeabilization with triton X-100 (Sigma-Aldrich). The fluorescent signal was visualized by a laser-scanning confocal microscope (LSM510, Germany).

Western blotting

Western blot analysis showed that S100 calcium binding protein A8 showed no difference in the protein expression when R.A. and N.A. cells were compared. Western blot analysis using antibodies associated with mitochondrial biogenesis showed that in all the samples with R.A. cells, the nuclear DNA (nDNA) encoded mitochondrial respiratory complex subunits; NDUFA9 of complex I and COX IV of complex IV were reduced compared to the N.A. cells (Fig. 1A). The Mitochondrial DNA (mtDNA)-encoded COX I subunit of complex IV was reduced or equivocal. Interestingly other nDNA-encoded subunits of complex II (SDHA), III (UQCRC2), and V (ATP5A1) did not differ in their expression in repeated experiments. The Western blot analysis of peroxiredoxin isoforms showed that Prx 1, Prx 2, and Prx 4 were consistently reduced compared to the N.A. cells; however, the Prx 3 and Prx 5 expression did not differ (Fig. 1B).

TMRE flow cytometry and confocal microscopy of mitochondria

The TMRE staining, representative of mitochondrial membrane potential showed that N.A. cells had stronger fluorescence by FACS (Fig. 2A). Mitotracker staining showed that the structure and content of mitochondria were not significantly different in the R.A. compared to the N.A. cells (Fig. 2B).

DISCUSSION

We isolated R.A. cells representative of a KSC enriched population and N.A. cells representative of TAC and differentiated cells. We used ACP-based PCR technology to identify DEGs between the R.A. and N.A. cells. ACP technology is based on the unique structure of a specific ACP...
which contains distinct 3' and 5' end regions separated by a regulator, and the interaction of each portion of this primer during two-stage PCR\textsuperscript{12,13}. This system facilitates the identification of DEGs from small samples without generating false positive results\textsuperscript{13}. The results of the experiments showed differences between R.A. and N.A. cells in mitochondria-related gene expression. The results showed that mitochondrial complex I, COX IV, Prx 1, Prx 2, and Prx 4 and the mitochondrial membrane potential were low in the R.A. cells compared to the N.A. cells. These consistent differences confirmed that this adhesion assay is useful for the isolation of KSCs.

Mitochondria are the major generators of cellular adenosine tri-phosphate (ATP) through oxidative phosphorylation\textsuperscript{16,17}. In addition, mitochondria are critical to both apoptosis and necrosis\textsuperscript{17}. The resistance of KSC's to damaging environmental stimuli\textsuperscript{10} may in part be due to the low activity of mitochondria. Similarly, human hematopoietic stem cells have low amounts of mitochondrial respiratory chain complexes and poor oxidative phosphorylation\textsuperscript{16}. The Low activity of mitochondria in R.A. cells may be related to low ROS generation in KSCs. Induction of mitogenic signaling causes the formation of ROS, which can also cause mitogenic stimulation\textsuperscript{18}. Thus low function or less differentiation of mitochondria may make KSCs, under stable conditions, divide slowly. In addition, mitochondrial dysfunction has been reported in human colon stem cells\textsuperscript{19}. Furthermore, another report showed that pathogenic mutations in the mitochondrial genome contributed to the promotion of cancer by preventing apoptosis\textsuperscript{20}; stem cells share with cancer cells the ability to escape from apoptosis\textsuperscript{21}.

The results of this study showed that Prx 1, Prx 2, and Prx 4 were low in the KSCs compared to the TACs. Prx is known to protect cells and tissues from oxidative damage by removing toxic hydrogen peroxide\textsuperscript{18,22,23}. Previously, Prx 1 and Prx 2 were found to have low levels of expression in undifferentiated human embryonic stem cells (ESCs) and increased levels in differentiated cells\textsuperscript{23-25}. The role of Prx 4 is not well known. A prior study showed that the mitochondrial mass was almost absent in the undifferentiated ESCs and dramatically appeared as differentiation progressed\textsuperscript{23}. In our study, a functional decrement, rather than a decreased amount, of mitochondria in the R.A. cells was observed; since mitotracker staining was stained regardless of the membrane potential. Reduction of complex I, a coordinator of other complexes\textsuperscript{25-27}, in the R.A. cells, suggests that the general mitochondrial complex activity was decreased in the KSC fraction. Complex IV includes the mitochondria-encoded enzymes, COX subunit I and subunit IV\textsuperscript{27}; therefore, reduction of components of complex IV in the R.A. cells may also support the low mitochondrial activity in the KSCs.

In comparison to the N.A. cell population, the R.A. cells exhibit lower levels of aerobic respiration-related proteins. R.A. cells may be less susceptible to oxidative damage. Taken together, our results suggest that reduced mitochondrial biogenesis may be a characteristic of KSCs. However, additional studies are needed to confirm this possibility.
