**Abstract:** Unipolar brush cells (UBCs) are excitatory interneurons with their somata located in the granular layer. Recently, T-brain factor 2 (Tbr2) was shown to be expressed in a subset of UBCs in mouse cerebellum. *Scrambler* mice exhibit severe cerebellum abnormalities, including the failure of embryonic Purkinje cell dispersal and a complete absence of foliation due to a mutation in the disabled-1 adaptor protein. Since most UBC markers are expressed postnatally, it has proven difficult to identify the relationship between developing Purkinje cell clusters and migrating UBCs. Because *scrambler* mice closely mimic normal embryonic day 18 cerebellum, we examined whether Tbr2-positive UBCs are associated with Purkinje cell cluster markers such as zebrin II, which is the most studied compartmentation marker in the cerebellum. We investigated the distribution of Tbr2-positive UBCs in this mutant by using anti-Tbr2 immunocytochemistry. The data revealed that Tbr2 immunoreactivity was exclusively present in the nucleus of UBCs in *scrambler* cerebellum. Based on expression data, a Tbr2-positive UBC map was constructed. In addition, Tbr2-positive UBCs are found associated with ectopic zebrin II-immunoreactive Purkinje cell clusters in *scrambler* cerebellum. These data suggest that UBCs use Purkinje cell compartmentation to migrate into their final position through interactions with the embryonic array of specific Purkinje cell subtypes.

**Key words:** Tbr2, unipolar brush cell, *scrambler*, zebrin, cerebellum

## Introduction

Unipolar brush cells (UBCs) are excitatory interneurons with their somata located in the cerebellum of granular layer (Altman & Bayer, 1977; Floris *et al.*, 1994; Mugnaini & Floris, 1994; Nunzi *et al.*, 2002). They are characterized by a small (9~12 µm) soma with a single short dendritic shaft and brush-like dendritic processes (Altman & Bayer, 1977; Mugnaini & Floris, 1994). In mice, UBCs are mainly present

in the posterior lobules (especially abundant in lobules IX and X, Nunzi *et al.*, 2002). They receive main excitatory inputs from the primary and secondary vestibulocerebellar mossy fibers (extrinsic mossy fibers) and project axons (intrinsic mossy fibers) that innervate both granule cells and other UBCs (Nunzi & Mugnaini, 2000; Nunzi *et al.*, 2001).

The mammalian cerebellum cortex is subdivided rostro-caudally and mediolaterally into a reproducible array of zones and stripes (for reviews see Hawkes & Gravel, 1991; Hawkes, 1997). The expression patterns of various Purkinje and granule cell antigens are restricted across zonal boundaries and have unique striped expression patterns within different zones (Hawkes & Eisenman, 1997; Ozol & Hawkes, 1997; Ozol *et al.*, 1999). In addition, the abnormal cerebellum phenotypes of certain mutant mice are regionally restricted

to particular zones (for reviews, see Armstrong and Hawkes, 2000; Eisenman, 2000). Among the compartmentation antigens in cerebellum, zebrin II is the most studied molecular marker. Zebrin II was first identified as the antigen that is recognized by a mouse monoclonal antibody produced by immunization with a crude cerebellum homogenate from the weakly electric fish *Apteronotus* (Brochu *et al.*, 1990). Zebrin II was later shown to be an epitope on the respiratory isoenzyme aldolase c (Aldoc: Ahn *et al.*, 1994). The zebrin II expression pattern consists of an array of parasagittal stripes displayed symmetrically on either side of the midline, each comprising a few hundred to a few thousand Purkinje cells.

T-brain factor 2 (Tbr2) -immunoreactive UBCs are expressed in a subset of UBCs (Englund *et al.*, 2006). It has proven difficult to identify the relationship between developing Purkinje cell clusters and migrating UBCs, since most UBC markers are expressed postnatally. During mouse cerebellar development, early Purkinje cell clusters disperse along the rostrocaudal axis around birth. The reelin-disabled-1 signaling pathway is known to mediate this process. *Scrambler* mice lack the disabled-1 gene, resulting in the failure of embryonic Purkinje cell clusters to disperse (Sweet *et al.*, 1996; Goldowitz *et al.*, 1997; Sheldon *et al.*, 1997: see also Howell *et al.*, 1997). Because *scrambler* cerebellar cortex mimics the topography of embryonic day 18 cerebellum, we examined whether Tbr2-positive UBCs are associated with Purkinje cell cluster markers. In this study, we show that Tbr2-immunoreactive UBCs are associated with specific zebrin II-positive Purkinje cell clusters in the mutant. These data suggest that UBC somata become restricted to stripes through interactions with the embryonic specific Purkinje cell clusters.

## Materials and Methods

### Mice

Postnatal day 60 male *scrambler* mice (N=4) and normal littermates (N=3) were obtained from the Jackson Laboratory, Bar Harbor, Maine, USA. The littermate controls gave identical results to those from the two outbred strains. The experimental procedures used in this study were followed and approved by the Animal Care and Use Committee of Konyang University, and these are consistent with NIH (Bethesda, MD, USA) guidelines.

### Antisera

Anti-zebrin II is a mouse monoclonal antibody produced by immunization with a crude cerebellum homogenate from the weakly electric fish *Apteronotus* (Brochu *et al.*, 1990): it was used directly from spent hybridoma culture medium at a concentration of 1 : 1,000. In the cerebellum, zebrin II immunoreactivity is restricted to a Purkinje cell subset (Brochu *et al.*, 1990) together with weak uniform expression in some glial cells. Affinity purified rabbit anti-Tbr2 was raised against mouse Tbr2 synthetic peptide (Englund *et al.*, 2006; Chemicon, Temecula, CA, USA, 1 : 1,000).

### Perfusion sectioning and immunohistochemistry

Mice were deeply anaesthetized with sodium pentobarbital (100 mg/kg, i.p.) and transcardially perfused with 0.9% NaCl in 0.1M phosphate buffer (PBS: pH 7.4), followed by 4% paraformaldehyde in 0.1M phosphate buffer (pH 7.4). The brains were removed from the skull and post-fixed in 4% paraformaldehyde at 4°C for 48 hours. The cerebellum was cryoprotected through a series of buffered sucrose solutions: 10% (2 hrs), 20% (2 hrs) and 30% (overnight). A series of 40 µm thick transverse sections were cut through the extent of the cerebellum on a cryostat and collected for free-floating immunohistochemistry. Briefly, tissue sections were washed thoroughly, blocked with 10% normal goat serum (Jackson ImmunoResearch Laboratories, West Grove, PA, USA) and then incubated in 0.1M phosphate buffered saline (PBS) containing 0.1% Triton-X and the primary antibody for 16~18 hours at 4°C. Secondary incubation in horseradish peroxidase (HRP) -conjugated goat anti-rabbit or HRP-conjugated goat anti-mouse antibodies (all diluted 1 : 200 in PBS; Jackson ImmunoResearch Laboratories) was for 2 hours at room temperature. Diaminobenzidine (DAB, 0.5 mg/mL) was used to visualize the reaction product. Finally, sections were dehydrated through an alcohol series, cleared in xylene and cover-slipped with Entellan mounting medium (BDH Chemicals, Toronto, ON, Canada).

Cerebellum sections for fluorescent immunohistochemistry were processed. Tissue sections were washed, blocked in PBS containing 10% normal goat serum (Jackson ImmunoResearch Laboratories), incubated in both primary antibodies overnight at room temperature, rinsed, and then incubated for 2 hours at room temperature in a mixture of Alexa 546-conjugated goat anti-rabbit Ig and Alexa 488-conjugated goat anti-mouse Ig (Molecular Probes Inc., Eugene, OR, USA), all diluted 1 : 2,000. After several rinses

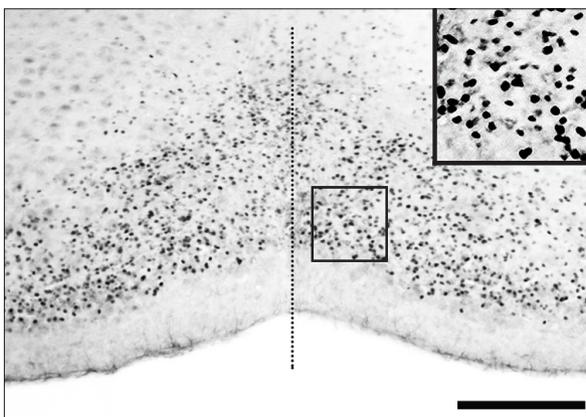

in 0.1M PBS, sections were coverslipped in non-fluorescing mounting medium (Fluorsave Reagent, Calbiochem, La Jolla, CA, USA).

Photomicrographs were captured with a SPOT Cooled Color digital camera (Diagnostic Instruments Inc, Sterling Height, MI, USA) and assembled in Adobe Photoshop. The images were cropped and corrected for brightness and contrast, but not otherwise manipulated.

## Results

### Unipolar brush cells express Tbr2 in the cerebellum of *scrambler* mice

Recently, we reported that UBCs are normally associated with Purkinje cell clusters, both in the perinatal and postnatal cerebellum, and Purkinje cell topography governs the UBC cluster distribution (Chung *et al.*, 2009). In this study, we applied a novel UBC marker and investigated its distribution in *scrambler* mutant cerebellum, in which Purkinje cells are located in ectopic clusters. In *scrambler* cerebellum, most anti-Tbr2 immunoreactivity is localized to a single interneuron type, the UBC (Fig. 1: Englund *et al.*, 2006). Tbr2 immunoreactivity is exclusively restricted to the nucleus - the somata, dendrites and axons are not labeled (Fig. 1A inset). No other cell type expresses Tbr2 in the cerebellum. Serial construction of the distribution of Tbr2-immunoreactive UBCs in

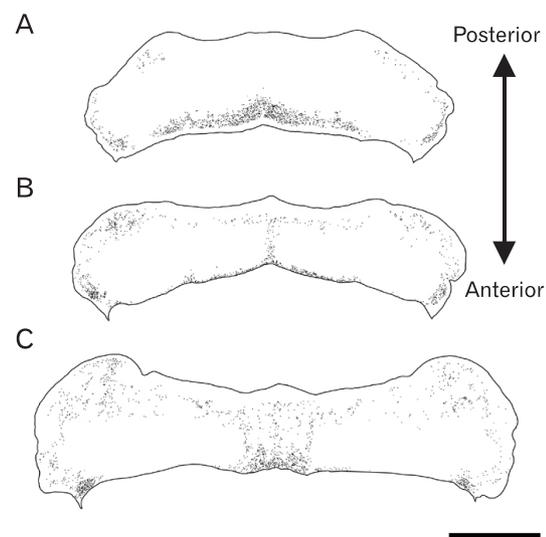

**Fig. 1.** Unipolar brush cells (UBCs) express Tbr2 in the cerebellum of *scrambler* mice. Transverse *scrambler* cerebellum section through the posterior lobe vermis immunoperoxidase stained with anti-Tbr2. Very strong immunoperoxidase products were deposited in individual cells. Tbr2 immunoreactivity is exclusively detected in the nucleus of UBCs. No other structures are stained. The rectangular layer is demonstrated with high-power image in inset. Midline is indicated by a dotted line. Scale bar = 125  $\mu$ m.

*scrambler* cerebellum is demonstrated in Fig. 2. Interestingly in *scrambler*, UBCs are located ectopically. In posterior cerebellum, Tbr2-positive UBCs are mainly present in the lower part of the vermis (Fig. 2A). Also, note that a few UBCs are observed in the hemisphere (Fig. 2A). In the anterior part of the *scrambler* cerebellum, the distribution of UBCs is concentrated in the midline portion and dorsal hemisphere region (Fig. 2B, C).

### Ubc's are associated with ectopic Purkinje cell clusters in *scrambler* mice

To identify the relationship between Purkinje cell subsets in *scrambler* mice, transverse sections were double stained for anti-zebrin II and anti-Tbr2 (Fig. 3). The ectopic clusters showed both zebrin II-positive and Tbr2-positive phenotypes, and Tbr2 expression reveals subdivisions within the population of zebrin II-immunoreactive Purkinje cells (Fig. 3). Supporting this observation, anti-Tbr2 and anti-zebrin II double stained sections, from the adult *scrambler* cerebellum, clearly show that Tbr2-immunoreactive UBC clusters are associated with ectopic Purkinje cell clusters in the posterior cerebellum (Fig. 3C, F). These data suggest that ectopic Purkinje cells might directly influence the positioning of Tbr2-immunoreactive UBCs by forcing them into abnormal locations.

**Fig. 2.** Serial reconstruction of the distribution of Tbr2-immunoreactive UBCs in *scrambler* mutant mice. (A) In posterior cerebellum, Tbr2-immunoreactive UBCs are mainly located in the ventral part of the vermis. (B~C) Middle and anterior part of the *scrambler* cerebellum. Tbr2-positive UBCs are present in the vermis and hemisphere region. Scale bar = 500  $\mu$ m.

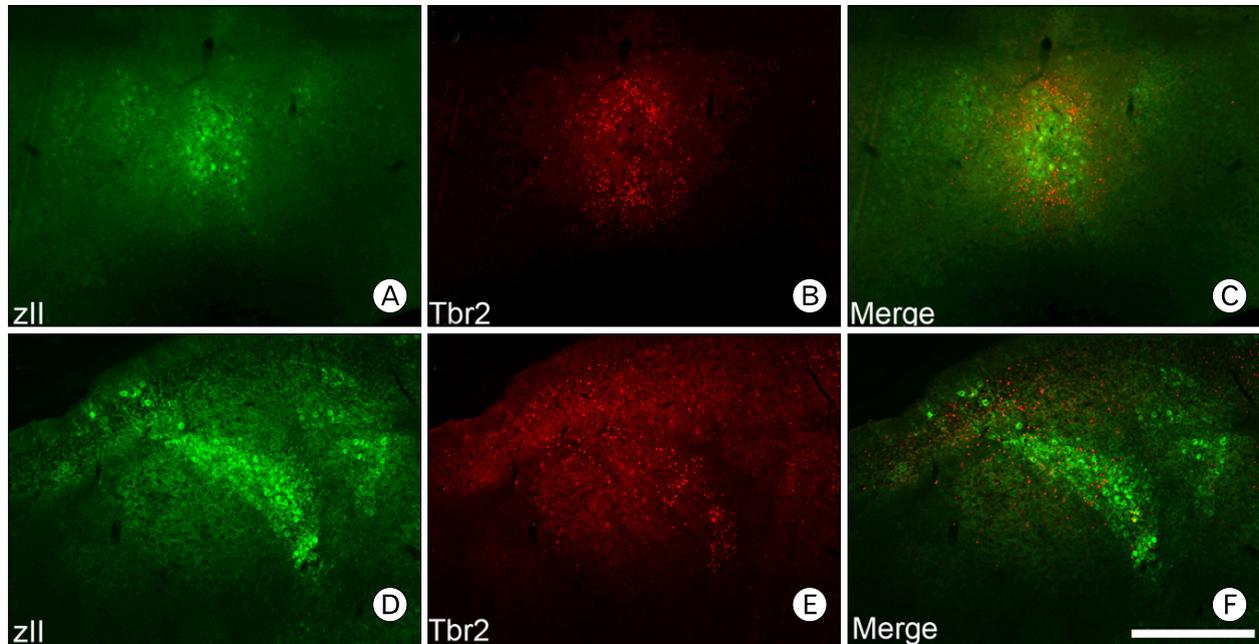

Fig. 3. A subset of Tbr2-immunoreactive UBCs is aligned with the zebrin II subset of Purkinje cells in the *scrambler* cerebellum. (A~C) Double immunofluorescence staining with anti-zebrin II and Tbr2 shows that ectopic Purkinje cells within the cerebellum express both zebrin II (green) and Tbr2 in *scrambler* vermis. (D~F) In *Scrambler* hemisphere, clusters of Tbr2-immunoreactive UBCs (red) are topographically aligned with a subset of zebrin II-immunoreactive Purkinje cells (green). Scale bar = 100  $\mu$ m.

## Discussion

Though lineage relationships are largely unknown (Abbott & Jacobowitz, 1995), UBCs are likely to behave similar to other cerebellum interneurons, which are born in the subventricular zone of the fourth ventricle and migrate out into the white matter tracts. Originally, UBCs are thought to arise from the fourth ventricle; however, more recent data suggest that their origin might be the rhombic lip (Englund *et al.*, 2006). The authors showed that rhombic lip ablation in slice cultures significantly reduced the number of Tbr2-positive UBCs. In addition, in *Math1* (molecular marker for rhombic lip and its derivatives) null cerebellum, the production of Tbr2-positive UBCs is decreased as well (Englund *et al.*, 2006). These data suggest that at least some populations of UBCs originate from the rhombic lip. UBCs are born earlier than cerebellum inhibitory interneurons and migrate into the developing cerebellum anlage shortly after deep cerebellum neurons and Purkinje cells (immature UBCs have been described in the mouse cerebellum as early as embryo age (E) 14: Abbott and Jacobowitz, 1995). By late embryogenesis, they encounter Purkinje cells that are already organized as discrete clusters. During postnatal development, UBCs and Purkinje cell clusters remain associated until

approximately P4. The data presented here for *scrambler* mice reveal an interaction between UBCs and Purkinje cell perinatal clusters that is preserved into adulthood due to the failure of reelin-disabled1 signaling.

Stripes of Purkinje cells form during cerebellum development through the dispersal of embryonic clusters, a process that requires the reelin-disabled-1 signaling pathway (Sweet *et al.*, 1996; Goldowitz *et al.*, 1997; Howell *et al.*, 1997; Sheldon *et al.*, 1997). In the mouse mutant *scrambler*, a lack of disabled-1 protein results in the failure of embryonic Purkinje cell cluster dispersal. Nevertheless, Chung *et al.*, (2009) showed that in the *scrambler* cerebellum, careltinin-immunoreactive UBCs are found to be associated with ectopic zebrin II-immunopositive Purkinje cell clusters. In this study, we further demonstrate that a novel UBC marker, Tbr2-immunoreactive UBCs, are also found to be associated with zebrin II compartments. The anatomical significance is that the presence of Tbr2-positive UBCs is not just restricted to posterior lobules, but is also in anterior lobules. In *scrambler*, Tbr2-positive UBCs are seen in the hemisphere region suggesting that this novel set of UBCs uses a different migratory pathway during embryonic development since *scrambler* cerebellum represents E18 cerebellum. Taken together, the data show

that the topography of UBCs is dramatically changed when Purkinje cells are located ectopically (*scrambler*), and this suggests that UBC somata become regionally restricted through interactions with the embryonic array of specific Purkinje cell subtypes. The mechanism that organizes the topography of the UBCs may mimic that for the mossy fibers. It has been suggested that mossy fiber topography is established through the interaction of their growth cones with the embryonic Purkinje cell topographical maps (e.g., reviewed in Sotelo & Chédotal, 2005). Mossy fibers are known to make direct contact with Purkinje cells as soon as they enter the cerebellum. Subsequently, mossy fiber growth cones detach from the Purkinje cells and make contacts in the granular layer - just beneath the Purkinje cells. This allows for the topographical relationship with the Purkinje cell compartments (Sotelo & Chédotal, 2005). The same may be the case for UBC topography, with UBCs behaving like mossy fiber growth cones: the embryonic Purkinje cell clusters would disperse into the adult array of stripes while taking the UBCs with them. This view is supported by the data on the distribution of UBCs in the *scrambler*. Since the *scrambler* cerebellum cortex represents the topography of the normal embryonic (E18) cerebellum, it is reasonable to speculate that the same relationship is true in the normal embryonic environment and that UBCs organize around embryonic Purkinje cell clusters. Thus, the simplest explanation is that the development of UBC topography is secondary to Purkinje cell compartmentation.
